This draft: November 2, 2020

Abstract

We define and document narrative conservatism. Using 10-Q and 8-K filings from 1993 to 2020, we analyze whether narrative disclosure responds to bad news in a more complete, news-consistent, and timely manner than to good news. We find that narrative disclosure is conservative. In particular, narratives are lengthier, timelier, and show greater tone consistency in response to bad news than to good news. Firms use lengthier 10-Q filings to clarify rather than obfuscate bad news, and report more 8-K filings and items in response to bad news than to good news. We provide initial evidence that narrative and conditional conservatism are complements. Finally, we document that narratives in the MD&A section and in voluntary disclosure are more conservative. Also, we find more narrative conservatism in settings where managers have strong incentives to disclose bad news.

Keywords: *Narrative Disclosure; Narrative Conservatism; Conservatism; Tone; Timeliness; Textual Analysis*

1 Introduction

We define and provide evidence of narrative conservatism. We define narrative conservatism as *narratives responding to bad news in a more complete, news-consistent and timely manner than to good news*. Our definition builds on the work of Basu (1997), extending the notion of accounting conservatism to narratives. Narrative conservatism is of interest for at least two reasons. First, narrative disclosure takes up a dominant space in corporate filings.¹ Investors' perceptions of firm performance and their subsequent decision-making processes are influenced by narratives (Li, 2011). Therefore, understanding the properties of narrative disclosure and their economic implications is essential for market participants and regulators. Second, studying narrative conservatism completes our understanding of accounting conservatism. If recognition is merely one of the presentation formats of financial reporting, then our extant knowledge of conditional and unconditional conservatism is a partial view of accounting conservatism (Kothari, Shu, & Wysocki, 2009; Guay & Verrecchia, 2018). Yet, we know little about whether narrative disclosure is conservative, or whether and how narrative conservatism interacts with the other forms of conservatism.

Prior studies distinguish between recognition and disclosure. Recognition is the depictions in numbers on the face of the financial statements, and disclosure is commonly viewed as the display in the notes and supporting schedules that accompany financial statements (Schipper, 2007). The two formats of financial reporting are subject to different reporting requirements. The Financial Accounting Standards Board (FASB) explicitly specifies a set of recognition criteria while allowing for more flexibility in disclosure (FASB, 1984). This flexibility paves the way for the supplementary role of disclosure—disclosing information that cannot be recognized due to the failure to meet one or more of the recognition criteria. The other explanatory role of disclosure is to provide detailed background information of recognized numbers in financial statements (FASB, 1984, par. 7).

Extensive research has been conducted on conditional and unconditional conservatism, focusing on properties of income statement and balance sheet items. Conditional conservatism captures the asymmetric response of *earnings* to positive and negative economic news, and unconditional conservatism manifests as a systematic understatement of *net book value of assets* due to prede-

¹ For example, Apple Inc.'s 2019 Annual Report contains only 3 pages of numerical summary in the financial statements and around 15 pages of other tables and figures, among a total of 64 pages. The rest of the report is devoted to narratives including risk factors, management discussion and analysis (MD&A), notes to financial statements (NFS), among other things. Also, over the past 20 years, the average number of pages in annual reports devoted to footnotes and MD&A has quadrupled (EY, 2012).

terminated aspects of the accounting process (e.g., Beaver & Ryan, 2005). However, conservatism in narrative disclosure is less studied (Kothari, Shu, & Wysocki, 2009; Guay & Verrecchia, 2018). To study narrative conservatism, we focus on whether narratives respond to economic losses (bad news) in a more complete, news-consistent and timely manner than to economic gains (good news). We concentrate on the completeness, news-consistency and timeliness of narratives because these three properties correspond to the three dimensions of disclosure. Completeness implies that disclosure should include all necessary information for a user to understand the underlying economic event (FASB, 2018a). News-consistency implies that disclosure should agree with the underlying economic event in terms of the content sentiment. Timeliness implies that disclosure should be made *in time* to be able to influence users' decisions (FASB, 2018a).

The existence of narrative conservatism is not clear ex-ante. Prior literature outlines several managerial incentives to disclose or withhold bad news (Healy & Palepu, 2001; Kothari, Shu, & Wysocki, 2009; Bao, Kim, Mian, & Su, 2019). We argue that these incentives also influence managers' decisions on whether, and to what extent their narrative disclosure responds to good and bad news asymmetrically. The three major considerations that drive narrative conservatism are cost of capital, managers' career and compensation incentives and litigation risk. Prior research on each of the three considerations provides mixed predictions regarding whether narratives are conservative.² Overall, whether *on average* firms respond to good and bad news asymmetrically in narrative disclosure remains an empirical question.

To test whether narrative disclosure is conservative, we proxy completeness by the number of total words in corporate filings. The more words a report contains, the more complete the narrative disclosure is. We interpret news-consistency as the degree to which firms responding to good news with positive tone and to bad news with negative tone, and we measure it by the marginal change of narrative tone in response to news. The marginal change of narrative tone depicts by how much the narrative tone changes given one unit change in stock returns. The greater the marginal change of narrative tone is, the more news-consistent the narrative disclosure is. We evaluate timeliness by the reporting time lag between news release and disclosure filing dates. The smaller the reporting time lag is, the more timely the narrative disclosure is. Overall, we posit that if narratives are conservative, disclosures should have more words, greater marginal change of tone and shorter

² See detailed discussions in Section 2.3. In an additional analysis, we perform a set of cross-sectional tests to examine narrative conservatism under these three considerations.

reporting time lag in response to bad news than to good news. In terms of news measurement, we follow Basu (1997) and use stock returns as a proxy for news.

We use two types of filings required by the U.S. Securities and Exchange Commission (SEC) for all public companies—10-Q and 8-K filings—as our narrative disclosure corpora. To begin with, we retrieve 10-Q and 8-K filings from the Electronic Data Gathering, Analysis, and Retrieval system (EDGAR) from 1993 to 2020.³ Next, we apply the financial sentiment word list developed by Loughran and McDonald (2011) (LM hereafter) to count the number of positive, negative, uncertainty, litigious and modal words in each corporate filing extracted from EDGAR. Finally, we construct NW as the natural logarithm of total words, TONE as the number of net positive words per thousand total words and TLAG as the number of days elapsed between the news release date and the SEC filing date. Our final 10-Q (8-K) sample consists of 91,606 (119,616) firm-quarter (firm-day) observations from 5,250 (8,261) unique firms. Our empirical results suggest that both 10-Q and 8-K filings have more words and greater marginal change in tone in response to bad news than to good news, consistent with narrative disclosure being conservative. In terms of reporting time lag, we find that 8-K filings respond more timely to bad news than to good news while 10-Q filings do not respond to good and bad news asymmetrically. Overall, we interpret the results as evidence of narratives being conservative in disclosure timeliness.⁴ Also, using the Gunning fog readability index, we find that the incremental length in bad news disclosure contributes to higher readability, suggesting that firms tend to use shorter and less complex words in disclosing bad news compared to good news, and this trend is aligned with the SEC advocacy of plain English writing. Moreover, we find that firms are more likely to report more 8-K items and 8-K filings in response to bad news than to good news.

Given the affirmative evidence of the existence of narrative conservatism, we then investigate how it interacts with conditional conservatism and other firm fundamental characteristics. We measure conditional conservatism with C_SCORE following Khan and Watts (2009). The firm

³ Since the SEC adopted the rule of electronic submission for corporate filings in 1993, data coverage in the first year of EDGAR implementation is low (Gao & Huang, 2020). We repeat our main analyses using data from 1994 onward, and our main results hold.

⁴ We draw the conclusion that narrative disclosure is conservative in terms of timeliness mainly based on the 8-K results because of two reasons. First, the 10-Qs are not as timely as the 8-Ks since the 10-Qs are periodic filings with relatively fixed reporting schedule, whereas the 8-Ks are designed to disclose any material corporate events at any point of time. Second, the 10-Qs not only contain narrative disclosure but also financial statements, whereas the 8-Ks contain mainly narrative disclosure, so the reporting time lag of 10-Qs does not strictly proxy for narrative timeliness. See Section 3.2 for detailed discussions.

fundamental characteristics that we look at are firm size (SIZE), growth opportunities (MTB) and leverage (LEV). We divide the full 10-Q sample into five subsample based on the quintiles of C_SCORE and each of the fundamental variables and estimate our main model within each subsample. We find that firms in the high conditional conservatism subsample are conservative in narratives as well, consistent with managers viewing narrative conservatism and conditional conservatism as complements. Also, we find that the smallest and the largest firms tend to be more conservative than the middle sized firms. Similarly, the rapidly-growing and the already-matured firms are more conservative than the firms with medium grow opportunities.

We perform three sets of additional analyses to explore other factors that affect narrative conservatism. First, to ensure that our results are not driven by boilerplate, which contain generic language that may contribute to narrative conservatism while offering little useful information to the users, we examine how narrative conservatism varies in MD&A and notes to financial statements (NFS). We conjecture that the MD&A narratives are more conservative than the NFS narratives because the former employ less boilerplate (SEC, 2019). We reconstruct the textual variables using texts from the MD&A and the NFS separately and repeat our main analysis. We find that MD&A narratives are conservative while the NFS narratives are not, confirming that our results are not driven by boilerplate.

Second, we study how narrative conservatism differs between voluntary and mandatory disclosure. Prior research suggest that voluntary disclosure provides a more comprehensive view for risks than mandatory disclosure (Nelson & Pritchard, 2016). Thus, we expect voluntary disclosure to be more conservative than mandatory disclosure, as managers have more freedom to determine the content and the rhetoric in voluntary disclosure and potentially deploy less boilerplate. We follow He and Plumlee (2020) to measure voluntary and mandatory disclosure using 8-K filings that contain voluntary and mandatory 8-K items. Consistent with our expectation, we find that narrative conservatism is mainly driven by voluntary disclosure.

Third, we inspect whether and how managerial incentives affect narrative conservatism in three settings where managers have strong incentives to disclose or withhold bad news. Prior studies document that when firms are undergoing a seasoned equity offering (SEO), managers have more incentive to withhold bad news (Teoh, Welch, & Wong, 1998; Lang & Lundholm, 2000). However, when executives anticipate large stock option grants, managers have more incentive to disclose bad news (Yermack, 1997; Aboody & Kasznik, 2000). We hypothesize and find evidence that the narrative disclosure of firms undergoing SEO is less conservative, whereas that of firms issuing

stock option grants is more conservative. Moreover, we find that firms with high litigation risk are less conservative compared to firms with low litigation risk in terms of disclosure completeness and news-consistency. Our finding echos with Rogers and Van Buskirk (2009) that firms reduce disclosure to avoid litigation, and provides indirect evidence to Francis, Philbrick, and Schipper (1994) that bad news disclosure may trigger litigation.

Finally, our results are robust to (a) employing alternative tone measure using positive and negative word list from the Harvard General Inquiry dictionary and (b) including controls for conditional conservatism and the managerial incentives.

Our study contributes to the accounting literature in four aspects. First, we document the existence of narrative conservatism. Prior literature focuses on two forms of conservatism—the asymmetric earnings responses to good and bad news and the understatement of net asset value (Basu, 1997; Ball & Shivakumar, 2005; Beaver & Ryan, 2005). We extend the notion of conservatism to the asymmetric narrative responses to good and bad news. Second, we add to the literature on the distinction and the interaction between recognition and disclosure (Aboody, 1996; Barth, Clinch, & Shibano, 2003; Schipper, 2007). We find that firms with high conditional conservatism tend to be more conservative in narratives as well, suggesting that recognition and disclosure are complementary forms of financial reporting. Third, we provide novel evidence to the debate regarding whether managers withhold bad news. Prior research uses a wide variety of disclosure proxies to study managers' tendency to disclose or withhold bad news (Kasznik & Lev, 1995; Kothari, Shu, & Wysocki, 2009; Bao et al., 2019). We use the textual properties of SEC filings as novel proxies for disclosure, and our results support the idea that firms on average disclose bad news in a more complete, news-consistent and timely fashion. Fourth, we relate to the broader literature on the informativeness of SEC filings. A stream of literature studies the market reactions to 8-Ks (Carter & Soo, 1999; Pinsker, 2006; Lerman & Livnat, 2010) and 10-K/Qs (Alford, Jones, & Zmijewski, 1994; Li, 2008, 2010). Instead, we use the market returns as indication of good and bad news for the firms and study the behavior of corporate narrative disclosure.

The rest of the study is as follows. Section 2 reviews prior literature and develops our main hypotheses. Section 3 outlines the empirical design and data selection process. Section 4 presents the main results. Section 5 reports the additional analyses and Section 6 concludes.

2 Theoretical Framework

2.1 Recognition and Disclosure

A stream of literature studies the distinctions between *recognition* and *disclosure* and their respective or combined effects (Aboody, 1996; Barth et al., 2003; Schipper, 2007). Schipper (2007, p. 301) defines recognition as “depictions in numbers with captions on the face of the financial statements” and disclosure as “display in the notes and supporting schedules that accompany financial statements.”⁵ In this study, we follow Schipper (2007) and use the terms *narratives*, *narrative disclosure* or *disclosure* interchangeably to denote all textual disclosures presented in SEC filings, including notes to financial statements, supplementary information and other means of financial reporting such as the MD&A section⁶.

Disclosure and recognition are subject to different reporting requirements. For an economic item to be recognized in financial statements, a set of recognition criteria needs to be satisfied. First, the item must meet the definition of an element of financial statements (definition criterion). Second, the item must have a relevant attribute measurable with sufficient reliability (measurability criterion). Third, the information about the item must be capable of making a difference in user decisions (relevance criterion). Fourth, the information must be representationally faithful, verifiable, and neutral (reliability criterion) (FASB, 1984). However, disclosure is more flexible because it can be deployed to disclose information that fails to meet certain recognition criteria (FASB, 1984, par. 7b).

Narrative disclosure plays an essential role in financial reporting, as FASB (1984, par. 7, CON5-7) states:

Although financial statements have essentially the same objectives as financial reporting, some useful information is better provided by financial statements and some is better provided, or can only be provided, by notes to financial statements or by supplementary

⁵ Statement of Financial Accounting Concepts No. 5—*Recognition and Measurement in Financial Statements of Business Enterprises* formally defines *recognition* as “the process of formally recording or incorporating an item into the financial statements of an entity as an asset, liability, revenue, expense, or the like. Recognition includes depiction of an item in both words and numbers, with the amount included in the totals of the financial statements.” (FASB, 1984, par. 6) but does not define *disclosure*. Due to the absence of a conceptual definition of disclosure, prior literature on disclosure commonly interpret disclosure as any display that is not in numbers. However, this interpretation may partially overlap with the FASB definition of recognition, which states that recognition also includes words. As Schipper (2007, p. 302) notes: “both in analytical modeling and in developing financial reporting concepts, it is difficult to distinguish between recognized and disclosed information.”

⁶ Because narrative disclosure in different sections may employ boilerplate to different extent, in additional analyses we examine narrative conservatism in the MD&A and the NFS sections separately.

information or other means of financial reporting.

Narrative disclosure has two fundamental functions. First, narratives can be supplementary to recognition, conveying information about corporate events that cannot be recognized due to the inability to meet one or more of the four recognition criteria. In terms of good news, because the good news requires higher verification in recognition, firms may convey good news via disclosure rather than recognition. For instance, under U.S. General Accepted Accounting Principle (GAAP), long-lived tangible and intangible assets cannot be revaluated upwards. So when the market price of the firms' long-lived tangible and intangible assets goes up, the firms cannot recognize the gain, but they may discuss the price movement in other filings. Regarding bad news, despite bad news already requires lower verification than good news, it may still not be fully recognized. For example, although firms could create a provision for the expected future payments from a potential lawsuit, they cannot recognize the associated reputation losses since it is extremely difficult to obtain a reliable estimate that can be verified subsequently. However, firms may discuss the likelihood and the expected reputation impact of entering into a lawsuit in the risk factors or the MD&A section of the SEC filings. Another example is that internally developed intangible assets cannot be capitalized, so they cannot be impaired when bad news arrives. However, firms may discuss the impact of news associated with these intangible assets in other filings. In sum, firms may use narrative disclosure to inform investors about the immeasurable, and thus irre recognizable impact of various corporate events and fulfill their obligation of providing relevant financial information to investors. Second, narratives can be explanatory to recognition, explaining the line items in financial statements. FASB (1984, footnote 4, CON5-7) gives several examples on the explanatory role of notes to financial statements:

For example, notes provide essential descriptive information for long-term obligations, including when amounts are due, what interest they bear, and whether important restrictions are imposed by related covenants. For inventory, the notes provide information on the measurement method used—FIFO cost, LIFO cost, current market value, etc. For an estimated litigation liability, an extended discussion of the circumstances, counsel's opinions, and the basis for management's judgment may all be provided in the notes. For sales, useful information about revenue recognition policies may appear only in the notes (FASB Statement No. 47, Disclosure of Long-Term Obligations; ARB No. 43, Chapter 4, "Inventory Pricing", statement 8; FASB Statement No. 5, Accounting for Contingencies, par. 10; and APB Statement 4, par. 199).

2.2 Definition of Narrative Conservatism

Extant literature documents conservatism in two forms: conditional and unconditional conservatism (Beaver & Ryan, 2005). Conditional conservatism manifests as “accountants’ tendency to require a higher degree of verification to recognize good news as gains than to recognize bad news as losses” (Basu, 1997, p. 7)⁷ and is typically measured by the asymmetric response of earnings to positive and negative stock returns. Examples of conditional conservatism include *impairments*, i.e., writing down by the amount of loss incurred, but not *revaluation*, i.e., writing up by the difference between market price and carrying amount, for long-lived tangible and intangible assets under U.S. GAAP, and lower of cost or market accounting (LCM) for inventory under U.S. GAAP or lower of cost or net realizable value accounting (LCNRV) under International Financial Reporting Standards (IFRS). Unconditional conservatism manifests as “accountants’ preference for accounting methods that lead to lower reported values for shareholders’ equity.” (Basu, 1997, p. 8) Examples of unconditional conservatism include the immediate expensing, rather than capitalizing of research and development (R&D) costs, and the use of accelerated depreciation for property, plant and equipment (Beaver & Ryan, 2005). Both conditional and unconditional conservatism affect line items in the financial statements.

Compared to the extensive research on conditional and unconditional conservatism in *recognition*, little is known about conservatism in *disclosure*. As Kothari, Shu, and Wysocki (2009, p. 243) state:

Considerable research examines conservative recognition in accounting in the United States and internationally (Basu [1997], Ball, Kothari, and Robin [2000], McNichols [1988]). However, there is little systematic evidence to suggest conservatism in firms’ disclosure practices, with the notable exception of disclosure of bad news to mitigate litigation risk.

In a recent analytical work, Guay and Verrecchia (2018, pp. 73-74) have expressed similar opinions:

By way of an analogy, 20 years ago, much of the accounting literature on transparent financial disclosure emphasized constructs such as earnings timeliness, high-quality accruals, and asset/liability recognition. Today, scholars study a plethora of additional financial disclosure mechanisms, including management forecasts, conference calls, management discussion and analysis (MD&A) disclosure, press releases, and social media outlets. A commitment to timely disclosure of bad news need not come exclusively

⁷ Basu (1997) does not use the terms conditional or unconditional conservatism. Here we quote Basu (1997) only to describe the manifestation of the two forms of conservatism, which are now labeled as conditional and unconditional conservatism.

through financial statement recognition, and we believe that a broader view of conservative disclosure will offer new paths forward for a literature that has struggled to develop theories to explain the efficiency of timely asymmetric earnings numbers. We encourage researchers to pursue these avenues to better understand how the very large literature on conservative financial reporting integrates with the equally large literature on corporate disclosure.

We answer the call to study conservatism in narrative disclosure. We define narrative conservatism as *narratives responding to bad news in a more complete, news-consistent and timely manner than to good news*. We focus on these three properties of narratives because they correspond to three independent information dimensions. Each narrative report can be conservative or not along each dimension.

First, the Conceptual Framework requires financial information to be *complete*. Complete disclosure must include all necessary information for a user to understand the underlying economic event (FASB, 2018a). Extant theoretical studies establish that managerial commitment to complete disclosure reduces information asymmetry and improves market efficiency (Glosten & Milgrom, 1985; Diamond, 1985; Diamond & Verrecchia, 1991; Baiman & Verrecchia, 1996). Empirically, Leuz and Verrecchia (2000) show that after German firms switched from the German reporting regime to the international reporting regime which requires an increased level of disclosure, their information asymmetry is reduced leading to lower cost of capital. Leuz and Schrand (2009) find that firms respond to the adverse shock created by the Enron scandal by increasing their disclosure level through lengthier 10-K filings, which reduces firms' cost of capital subsequently. Given the significant economic impact, completeness constitutes an essential attribute of disclosure.

Second, we introduce the concept of *news-consistency* to assess *how* information is provided, and we interpret it as the degree to which firms use positive tone in response to good news and negative tone in response to bad news in narrative disclosure. As the old adage goes, "It's not what you say; it's how you say it." Rhetoric can be employed to mislead the market. For example, Huang, Teoh, and Zhang (2014) document that firms strategically engage in upward tone management to boost investors' perception of firm performance. Given that news-consistency, i.e., whether and to what extent corporate disclosure aligns with the real impact of the underlying economic event is likely to affect market reactions to the disclosure, it is qualified as a critical attribute of disclosure.

Third, the Conceptual Framework requests financial information to be *timely*. Specifically, disclosure should be made *in time* to be able to influence users' decisions (FASB, 2018a). Several studies document that reporting timeliness subjects to managerial discretion and therefore has information content which influences market reaction to the disclosure. For Instance, using annual

and interim earnings announcements of 100 firms listed on NYSE from 1970 to 1976, Chambers and Penman (1984) find that firms accelerate good news disclosure while delay bad news disclosure, and that investors interpret the failure to report on time as a forecast of bad news. Alford et al. (1994) find that firms that fail to meet the annual report submission deadline are on average small, have negative accounting rates of return, negative earnings changes, low liquidity, and high financial leverage, and that the market reacts negatively to the filing delay of 10-Ks. Given the negative economic consequences of late disclosure, we propose timeliness as one important attribute of disclosure.

2.3 To Be or Not to Be Conservative?

The existence of narrative conservatism is not clear ex-ante. Building on the prior literature regarding managerial incentives to disclose or withhold bad news (Kasznik & Lev, 1995; Kothari, Shu, & Wysocki, 2009; Bao et al., 2019), we propose three factors that influences firm decisions on whether, and to what extent their narrative disclosure responds to good and bad news asymmetrically. The first factor is cost of capital. Guay and Verrecchia (2018, p. 73) show that conservative reporting, defined as “firms disclosing bad realizations of economic events”, results in lower cost of capital and higher firm value. Specifically, the authors point out that “because our model focuses on timely information disclosure, we interpret the financial reporting system broadly to include not only reported earnings or balance sheet accounts, but also required footnotes or explanations in firm reports, as well as any number of other required disclosure formats.” (Guay & Verrecchia, 2018, p. 73) In line with their predictions, García Lara, García Osma, and Penalva (2011) find that conditional conservatism effectively lowers firms’ cost of capital by reducing information uncertainty and the volatility of future stock prices. Thus, managers have incentives to commit to conservative reporting in narrative disclosure to obtain lower cost of capital. However, in contrast to the notion that firms disclosing bad news reduces cost of capital, Kothari, Li, and Short (2009) illustrates that favorable disclosure decreases cost of capital while unfavorable disclosure increases it significantly. This penalization of bad news disclosure from frictional capital market induces managers to disclose good news and withhold bad news, leading to an asymmetric disclosure behavior but to the opposite direction of narrative conservatism. Consistent with this argument, Teoh et al. (1998) and Lang and Lundholm (2000) find that firms undergoing equity issuance tend to disclose good news and withhold bad news. Overall, whether the incentive to lower firms’ cost of capital drives narrative disclosure to be conservative is not clear.

The second factor is managers' career concern and compensation incentives. Skinner (1994) argues that managers may face reputational costs if they fail to disclose bad news in a timely manner prior to a negative earnings surprise. Yermack (1997) and Aboody and Kasznik (2000) document that managers release bad news prior to stock option grant dates to lower the option strike price. However, because significant bad news affects managerial reputation and wages negatively, managers may withhold bad news, expecting to be able to hide bad news by aggregating them with subsequent news on positive corporate events (Segal & Segal, 2016; Chapman, Reiter, White, & Williams, 2019). Baginski, Campbell, Hinson, and Koo (2018) also document that firms' delay of bad news is positively associated with managerial career concerns. Based on these studies, we argue that during times when managers have strong incentives to manipulate firm performance downwards (upwards) by disclosing (withholding) bad news to fulfill their personal objectives, they may simultaneously delay (accelerate) good news disclosure, or disclosing good news in a less (more) positive tone or with less (more) words, thus creating asymmetric disclosure behaviors in response to good versus bad news. Overall, whether managers' career concern and compensation incentives drive narrative disclosure to be conservative is unclear.

The third factor is litigation risk. Because financial information users have asymmetric preference for unexpected gains and losses (e.g., Lleras, Piermont, & Svoboda, 2019), they are more likely to sue the firm when they face negative earnings surprises than positive earnings surprises. Skinner (1994, 1997) document that firms preempt negative earnings surprises with voluntary bad news disclosure to avoid being sued or to minimize the costs of resolving the litigation that inevitably follows the disclosure of bad news. Field, Lowry, and Shu (2005) find that disclosure of bad news deters certain types of litigation. Rogers, Van Buskirk, and Zechman (2011, p. 2179) suggest that "managers can reduce litigation risk by dampening the tone of their earnings announcements either by decreasing their use of positive language or by tempering their optimism with statements that are less favorable." Moreover, in a continuous-time disclosure model, Marinovic and Varas (2016) show that litigation risk not only leads to early disclosure of bad news, but also suppresses good news disclosure since the market interprets silence as good news and firms can communicate good news without actually disclosing it, saving proprietary disclosure costs. Based on the above arguments, firms may disclose bad news in a more complete, news-consistent and timely manner than good news to avoid litigation. However, Francis et al. (1994) find that earnings warnings tend to be followed by securities lawsuits, suggesting that bad news disclosure actually triggers litigation. Aligned with this argument, Rogers and Van Buskirk (2009) find that firms reduce the frequency

and amount of disclosure post-litigation, suggesting that firms become more likely to withhold bad news for which they may later be held accountable. Overall, whether litigation risk drives narrative disclosure to be conservative is unclear.

To summarize, in the presence of various managerial incentives, whether narratives are conservative *on average* remains an empirical question. Thus, we formulate our hypotheses on the existence of narrative conservatism as follows:

H1: *Narrative disclosure is more complete in response to bad news than to good news.*

H2: *Narrative disclosure is more news-consistent in response to bad news than to good news.*

H3: *Narrative disclosure is more timely in response to bad news than to good news.*

3 Research Design

3.1 Empirical Proxy

We use length, marginal change of tone and reporting time lag as proxies for disclosure completeness, news-consistency and timeliness respectively. Specifically, We measure disclosure completeness by the total number of words of SEC filings. The Conceptual Framework requires complete disclosures to include “all information necessary for a user to understand the phenomenon being depicted, including all necessary descriptions and explanations.” (FASB, 2018a, QC12) Hence, more complete disclosure should be lengthier, which allows managers to elaborate on detailed explanations of firm performance (Leuz & Schrand, 2009).⁸ However, we are aware of a strand of literature suggesting that narrative disclosure is less informative when it is less readable (Li, 2008; Lo, Ramos, & Rogo, 2017; Loughran & McDonald, 2014), and because lengthier documents are often less readable, it may appear counter-intuitive to proxy completeness with the document length. We provide two explanations for this measurement. First, some studies point out that instead of managers’ intentional obfuscation, lower readability may result from the fact that bad news is inherently more complex and therefore needs more explanations (Bloomfield, 2008), and that

⁸ We use number of words instead of number of pages, which is used in Leuz and Schrand (2009), as the proxy for disclosure completeness for two reasons. First, for pure texts, these two measures are almost equivalent, or at least are monotonic transformations of each other, given a roughly constant number of words per page. Second, for financial reports with graphs and tables, the number of words is a more precise measure for narrative disclosure, because it counts the length of narratives only. However, the number of pages may be enlarged mechanically by graphs, tables, and even space lines embedded in the tables, which are not the focus of this study.

there is incremental information content embedded in complex narratives (Bushee, Gow, & Taylor, 2018). Therefore, lower readability does not necessarily imply lower narrative disclosure quality. Second, although somewhat correlated, the document length and the readability are essentially two different constructs. Texts can be long or short, readable or unreadable independently. Specifically, in measuring information completeness, the document length is an appropriate construct because “including all necessary descriptions and explanations” (FASB, 2018a, QC12) in narrative disclosure inevitably increases the document length. In an additional test, we address this concern by directly testing whether narrative disclosure respond asymmetrically to good and bad news in terms of readability. Given the arguments above, if narrative disclosure is conservative, we expect it to have more words in response to bad news than to good news.

We proxy the sentiment spectrum in narrative disclosure by linguistic tone and measure the degree of news-consistency by the marginal change of tone in response to unit increase (good news) or decrease (bad news) in stock market returns. News-consistency requires the marginal change to be positive, so that the positive tone responds to good news and the negative tone to bad news. Furthermore, if the narrative tone is more consistent for bad news than for good news, it implies greater marginal change of tone in response to bad news than to good news. That is, the change in narrative tone should be more negative in response to bad news than it should be positive in response to good news, given the same magnitude of news impact. Narrative conservatism creates a downward bias in tone, irrespective of the nature of news: either bad news is emphasized or good news is attenuated, or both.⁹ If narrative disclosure is conservative, we expect it to have greater marginal change of tone in response to bad news than to good news.

We measure timeliness by the reporting time lag, defined as the number of days elapsed between the news release date and the filing date of the narrative disclosure.¹⁰ Specifically, in the 10-Q

⁹ We provide the following numerical example to illustrate the concept of marginal change of tone. Suppose that there is 1% increase (good news) and 1% decrease (bad news) in stock return, which should move tone upwards and downwards by 1% in theory if the response of narrative tone is neutral, i.e., tone equally responding to good and bad news. However, in the presence of narrative conservatism, three situations may happen: (1) bad news emphasis: in response to bad news, tone decrease by 1.2% and in response to good news, tone increase by 1%; (2) good news attenuation: in response to bad news, tone decrease by 1% and in response to good news, tone increase by 0.8%; (3) a mix of both: in response to bad news, tone decrease by 1.2% and in response to good news, tone increase by 0.8%. In all cases, the marginal change of tone in response to bad news is greater in magnitude than that in response to good news. Therefore, under narrative conservatism, the marginal change of tone in narrative disclosure is greater in response to bad news than to good news.

¹⁰ One concern of the TLAG measurement for reporting timeliness is that the length of reporting time lag may not be fully controlled by managers, and thus cannot accurately capture the discretionary reporting timeliness of firms. Prior auditing literature suggests that a set of auditor characteristics contributes to unexpected audit report lag (Knechel & Payne, 2001; Bamber, Bamber, & Schoderbek, 1993), which leads to filing delay in audited financial

sample, it is calculated as the number of days elapsed between the quarter-end and the filing date of the corresponding 10-Q. In the 8-K sample, it is calculated as the number of days elapsed between the news day, i.e., the nearest date around an 8-K reporting period date when there is a dramatic change in stock daily returns, and the filing date of the corresponding 8-K. The shorter is the reporting time lag, the more timely is the narrative disclosure. If narrative disclosure is conservative, we expect it to have shorter reporting time lag in response to bad news than to good news.

Following Basu (1997), we measure good and bad news with stock returns. In efficient market, stock returns incorporate public and private information in a timely manner and therefore the positive and negative returns are indicative of good and bad news of firms. Firms respond to the news by disclosing detailed information of the events that cause changes in stock returns via the 10-Q or 8-K filings.

3.2 Narrative Disclosure Corpora

We study narrative disclosure using 10-Q and 8-K filings from EDGAR database as our corpora. The form 10-Q is a comprehensive report that depicts quarterly firm performance, and it must be filed by all public companies to the SEC within 40 (for accelerated filers) or 45 days (for all other registrants) after fiscal quarter-end, according to Section 13 or 15(d) of the Securities Exchange Act of 1934. The form 8-K is a report that all public firms must file to the SEC to notify investors about material events or changes in the company, where each type of event is classified as an *8-K item*. Appendix A provides a full list of 8-K items. The 8-K items are listed in two distinct formats before and after August 23 of 2004 because on that date the SEC adopted an 8-K reform, which made three amendments to the prior 8-K guidance: expanding the scope of the events subject to Form 8-K disclosure, creating a new topical format, and shortening the filing deadline (SEC, 2004; Lerman & Livnat, 2010). All 8-K items except the Other Events, the Regulation FD Disclosure and the Results of Operations and Financial Condition are mandatory items.¹¹ For mandatory items, the 8-K filings must be filed upon the occurrence of any one or more events pertaining

reports consequently. However, because audit for quarterly filings is not mandated by law, and due to the high auditing cost and limited time constraint, most 10-Q filings are not audited.

¹¹ We follow He and Plumlee (2020) and classify the Results of Operations and Financial Condition and the Regulation FD Disclosure as voluntary disclosure items, because the triggering event of these two items is the firm's voluntary disclosure of material events. Lerman and Livnat (2010) classify the two items as "semi-voluntary" based on the same reason. The item Other Events is voluntary following the filing requirement in SEC (2004).

to the mandatory 8-K items within a specific filing deadline. The filing deadline for mandatory items ranged from five to fifteen days after the occurrence of the event in the late 1980s, and was shortened to four business days following the occurrence of the event after August 23 of 2004 (Lerman & Livnat, 2010).

Firms issue narrative disclosure via multiple channels, such as social media and press, conference calls and annual reports etc. We focus on the 10-Q and 8-K filings in this study for three motives. First, the 10-Q and 8-K filings are both firm-issued filings that are required for all public companies. Their contents are under SEC scrutiny and biased reporting increases litigation risk (Rogers, Van Buskirk, & Zechman, 2011). Therefore, 10-Q and 8-K filings provide higher credibility compared to firm-issued disclosures via social media and press. Second, the 10-Q and 8-K filings are highly scripted and have higher reporting threshold compared to conference calls, meaning that the corporate events need to have a moderate impact on firm operations in order to be discussed in the 10-Q and 8-K filings (Hassan, Hollander, van Lent, & Tahoun, 2019). Hence, we filter out less relevant events and concentrate on the ones with material impact by using 10-Q and 8-K reports. Third, the 10-Q and 8-K filings are more timely than the 10-K filings, i.e., annual reports. Using the 10-K filings, managers can only bundle information acquired during the whole fiscal year and make summarized responses to all events in one single report at year-end. Given that one of our goals is to examine the timeliness of narrative disclosure, the 10-K filings cannot provide sufficient time variation in good and bad news responses, and thus they are not appropriate text source for the purpose of this study.

There is heterogeneity between 10-Qs and 8-Ks as well. First, the 10-Qs provide more variation and diversity than 8-Ks in terms of content. The 10-Qs contain sections such as the NFS and the MD&A, where managers can discuss the economic implications of significant corporate events and issue forward-looking statements, whereas the 8-Ks only offer event descriptions in a relatively standardized format. Moreover, the 8-Ks are shorter, i.e. contain fewer words than the 10-Qs on average. These features imply that the 10-Qs are more flexible in content, in the sense that managers have more discretion on what and how to disclose in the 10-Qs, which provides us with more variation in linguistic tone than 8-K filings. Thus, our analyses and conclusions regarding linguistic tone are mainly conducted on and drawn upon the 10-Q sample.

Second, the 10-Qs are not as timely as the 8-Ks. The 10-Qs are filed only once every quarter, so regardless of managerial reporting incentive, the 10-Qs cannot be as timely as the 8-Ks in responding to unexpected corporate events, especially for those events that happen during early

days in a fiscal quarter. This is testified by the following excerpt extracted from SEC (2004):

Under the previous Form 8-K regime, companies were required to report very few significant corporate events. The limited number of Form 8-K disclosure items permitted a public company to delay disclosure of many significant events until the due date for its next periodic report. During such a delay, the market was unable to assimilate such undisclosed information into the value of a company’s securities. The revisions that we adopt today will benefit markets by increasing the number of unquestionably or presumptively material events that must be disclosed currently. They will also provide investors with better and more timely disclosure of important corporate events.

Furthermore, besides narrative disclosure, the 10-Qs also contain quarterly financial statements, so the reporting time lag of the 10-Qs does not strictly measure the timeliness of narrative disclosure solely, but the timeliness of recognition and disclosure in aggregation. Considering these features, our analyses and conclusions regarding timeliness are mainly conducted on and drawn upon the 8-K sample.

3.3 Model Specification

3.3.1 Form 10-Q

The 10-Q filings are quarterly reports that are filed to SEC within 40 or 45 days after fiscal quarter-end. Given their stable periodicity, we design the following model to explore how the 10-Q filings respond to good versus bad news.

$$TEX_{i,t} = \beta_0 + \beta_1 QRET_{i,t} + \beta_2 NEG_{i,t} + \beta_3 QRET_{i,t} \times NEG_{i,t} + \beta_n CONTROLS_{i,t} + \epsilon_{i,t} \quad (1)$$

In Equation 1, QRET denotes the quarterly market-adjusted stock returns. NEG is an indicator for bad news, which is set to 1 if QRET is negative and 0 otherwise. CONTROLS represents a vector of control variables. We control for a set of firm fundamental characteristics proposed by Li (2010) that can affect narrative disclosure to alleviate the omitted variable bias. We control for firm size by the market value of equity (SIZE), as larger firms may have lengthier and more cautious narratives. We control for growth opportunities by market-to-book ratio (MTB), as growing firms may face more uncertainties which contributes to more detailed and more cautious narratives. We control for leverage ratio (LEV) because highly leveraged firms are more conditionally conservative due to strong demand from lenders (Watts & Zimmerman, 1986; Watts, 2003), and analogously those firms may also under high pressure from lenders to provide more detailed narrative disclosure such as accompanying notes on loan terms and investments. We control for life cycle stage

of the company by age (AGE), as young firms may face more uncertainties which lead to more cautious narratives. We control for operating complexity of the firm by the number of business segments (BUSSEG) and geographical segments (GEOSEG), as more complex operating environment may lead to more complex disclosure. We control for profitability by earnings (EARN), as the narrative tone of firms with good (bad) operating performance may be inherently positive (negative). We control for operating risks by the volatility of stock returns (STD_RET) and earnings (STD_EARN), because risk factors need to be disclosed with more detailed and more cautious narratives. We control for the expectations of future financial performance by analyst earnings forecast (AF) and analyst forecast error (AFE) following Huang et al. (2014). Detailed variable definitions are provided in Appendix B.

Notice that the right-hand side of Equation 1 resembles the conditional conservatism model in Basu (1997). Our model differs from the Basu model in replacing earnings with three textual variables to examine the responses of narrative disclosure to positive versus negative market returns. Specifically, TEX represents a vector of textual properties that consists of number of words (NW), tone (TONE) and reporting time lag (TLAG). NW is calculated as the natural logarithm of one plus the count of total words. TONE is defined as number of net positive words per thousand total words, and is calculated as total number of positive words minus the sum of total number of negative words and total number of negations, and multiply the previous result by one thousand for the ease of interpretation. We follow LM and count negations as cases where negation words¹² occur within four or fewer words from a positive word. By taking negations of positive words into consideration in calculating tone, we control for the fact that it is common for firms to frame bad news using negated positive words, i.e., use “did not increase” instead of “decrease”. We do not control for negations of negative words because firms rarely communicate good news with negated negative words, i.e., use “did not fail” instead of “succeeded” (Loughran & McDonald, 2011). TLAG is defined as number of days elapsed between the fiscal quarter-end and 10-Q filing date in EDGAR. Additionally, we measure the readability of 10-Qs using the Gunning fog index following Li (2008). The fog index is positively correlated with the average number of words per sentence and the percentage of complex words in a document. The higher the index is, the less readable the document is.

The coefficient of interest in Equation 1 is β_3 , which we interpret as the difference in respon-

¹² Negation words include: no, not, none, neither, never, nobody (Tottie, 1991).

siveness of textual properties to good versus bad news. If 10-Q narrative disclosure is conservative, we expect it to have more words, greater marginal change of tone and shorter reporting time lag in response to bad news than to good news. In the case of NW being the dependent variable, β_3^{NW} should be negative under H1. Because QRET is always negative when NEG equals 1, the interaction term $\beta_3^{NW} QRET_{i,t} \times NEG_{i,t}$ is positive only when β_3^{NW} is negative, which translate into more words. Following the same logic, β_3^{TLAG} of TLAG regression should be positive under H3, which translates into shorter reporting time lag. The interpretation of β_3^{TONE} is different from those of the previous two models, in the sense that β_3^{TONE} represents the difference in marginal change of tone in response to good versus bad news. An incremental marginal change of tone in response to bad news relative to good news is reflected as positive β_3^{TONE} .

3.3.2 Form 8-K

Due to the irregularity and unpredictability of the 8-K triggering events, the 8-K filings in EDGAR database have a unique data structure: though most companies only report one 8-K filing in one day and each 8-K filing usually contains only one or two 8-K items, some firms report more than one 8-K filing per day and each 8-K filing may contain more than two items. So we construct our 8-K sample in three steps. First, we aggregate the raw 8-K data at individual filing level into firm-day level by summing up all raw count variables over each firm-day. For instance, the count variable $nw_{i,t}$ in 8-K sample stands for number of total words in all 8-K filings reported in day t for firm i , instead of number of total words of one specific 8-K filing. To keep track of the unique data structure of 8-K filings, we further construct two new variables—N8K and NITEM, which are defined as the number of 8-K filings and the number of 8-K items in one reporting period date, respectively.¹³ We label a firm-day as “8-K day” if at least one 8-K’s reporting period date coincides with that day.

Next, we build our proxy for news under 8-K context. We obtain the daily market-adjusted stock returns (DRET) and calculate the change in daily returns ($\Delta DRET$). Then, we define a firm-day as a “bad (good) news day” if the negative (positive) change in daily market-adjusted stock return ($\Delta DRET$) is three times larger than the firm’s average decrease (increase) in daily return over the calendar year. BN is an indicator for bad news day, which is set to 1 if the firm-day is a

¹³ All filings in EDGAR have two dates: filing date and reporting period date. Filing date is the date when the report is filed to EDGAR, and reporting period date is the end date of reporting period of the filing (see <https://www.sec.gov/about/webmaster-faq.htm>).

bad news day, and 0 if the firm-day is a good news day.¹⁴ Notice that we define good and bad news differently under 8-K and 10-Q context. This is because that the daily returns are more volatile than quarterly returns and the sign of daily returns can change constantly merely due to trading noises. Therefore, we only focus on firm-days with sizable changes in daily returns, which are more likely to result from significant corporate events and reflect fundamental firm information.

Then, we conduct a matching process as illustrated in Figure 1. The idea of matching is to pair the firms' news releases and 8-K filings. Specifically, we match every 8-K day to its nearest news day. The matched news day can be earlier than (Match-1), the same as (Match-2) or later than (Match-3) the 8-K day. After matching, we calculate TLAG of 8-K sample as the number of days elapsed between the 8-K filing date and its nearest news day.¹⁵ We eliminate all Match-3 cases in which the market return movements occur after the filing of 8-Ks, because for this type of match we cannot accurately identify the date when the underlying event actually occurs.¹⁶ Our final 8-K sample consists of Match-1 and Match-2 with non-negative TLAG.

The underlying assumption behind this matching process is that the 8-K filing and its nearest news release are triggered by the same underlying event. One concern of this assumption is that the 8-K filing and the news release may not be about the same event even if they are close in time. We provide two validity checks for this assumption from different aspects. As a first check, we construct a *restricted 8-K sample* by limiting the full 8-K sample to observations with reporting time lag less than or equal to four (five) calendar days for observations with reporting period date after (before) August 23 of 2004 ($\text{TLAG} = 0, 1, 2, 3, 4, 5$). Because firms must file required 8-Ks within four (five) business days of a triggering event after (before) August 23 of 2004 (SEC, 2004), 8-K filings reported within four (five) days of the news release date are more likely to be related to the precedent news, as is regulated by the SEC rule.¹⁷ As a second check, we conduct a manual

¹⁴ We code BN to missing if the firm-day does not have any news. Therefore, all observations in our final 8-K sample are either good or bad news firm-days.

¹⁵ We match 8-Ks to news by *reporting period date* because the reporting period date and the news release date are both about the actual date when the underlying event takes place. However, we calculate TLAG using 8-K *filing date* because we are interested in whether 8-Ks are filed in response to good and bad news with different timeliness, allowing for managerial discretion in reporting speed.

¹⁶ We do not use the lag between the 8-K reporting period date and the 8-K filing date to measure reporting time lag as in prior literature (Carter & Soo, 1999; Niessner, 2015; Chapman et al., 2019) because of two reasons. First, the reporting period date is the latest possible date, but not necessarily the exact date at which the underlying event occurs (SEC, 2004). Second, this reporting period date is self-reported by managers. Therefore, managers may have incentives to prolong or shorten the lag, which creates endogeneity concerns (Chapman et al., 2019). In an untabulated robustness check, we include the Match-3 observations into our 8-K sample and calculate their TLAG as the number of days elapsed between the 8-K reporting period date and the 8-K filing date, and our results sustain.

¹⁷ Our restricted sample selection criterion is more restrictive than the SEC rule for three reasons. First, while the

audit for 20 matched 8-K cases, and the results support the matching assumption that the 8-Ks are responses to their matched news releases. See Appendix C for details of the manual audit process.

Once the 8-K sample is constructed, we design the following model to explore how 8-K filings respond to good versus bad news.

$$TEX_{i,t} = \beta_0 + \beta_1 \Delta DRET_{i,t-tlag} + \beta_2 BN_{i,t-tlag} + \beta_3 \Delta DRET_{i,t-tlag} \times BN_{i,t-tlag} + \beta_n CONTROLS_{i,t} + \epsilon_{i,t} \quad (2)$$

Where $\Delta DRET$ and BN are changes in daily returns and bad news indicator *at news release date*. We deploy $\Delta DRET$ rather than $DRET$ in this model because under 8-K context, the bad news indicator BN is defined based on $\Delta DRET$ instead of $DRET$. In Equation 2, $CONTROLS$ denotes a vector of control variables at 8-K *filing date*, including firm size ($SIZE$), market-to-book ratio (MTB) and leverage ratio (LEV).¹⁸ TEX represents a vector of textual properties that consists of number of words (NW), tone ($TONE$) and reporting time lag ($TLAG$). The coefficient of interest in Equation 2 is still β_3 , and its interpretation is the same as that in the context of 10-Q. If 8-K narrative disclosure is conservative, we expect it to have more words, greater marginal change of tone and shorter reporting time lag in response to bad news than to good news, which manifests as negative β_3^{NW} , positive β_3^{TONE} and positive β_3^{TLAG} .

3.4 Data

We obtain historical financial and segment data from Compustat, stock returns from the Center for Research in Security Prices (CRSP) and analyst earnings forecasts data from I/B/E/S. We retrieve 10-Q and 8-K data from EDGAR through a self-developed Python program (see Appendix D for detailed description of EDGAR data collection process). Table 1 illustrates the sample selec-

regulation requires firms to file 8-K within four (five) business days of a triggering event, we reduce this reporting deadline to four (five) calendar days, which is always shorter or at most equal to four (five) business days. Second, the regulation exempts the voluntary disclosure items from the four (five) business day reporting deadline (He & Plumlee, 2020), but we still apply this reporting deadline to these items. Third, prior to the 8-K reform, 8-Ks must be filed within five to fifteen days depending on the nature of the event occurred, but we uniformly apply the five days deadline to all items before the reform. This more stringent sample selection criterion further ensures that the 8-K filings in our restricted sample are indeed responding to the precedent news.

¹⁸ Because our measures of firm fundamentals are calculated based on Compustat quarterly data, the variation in firm fundamental measures is very small (if any) either we control for them at news release date ($t-tlag$) or at 8-K filing date (t), as the average reporting time lag of 8-K is only 15 days. Due to the same data frequency mismatch issue, we only control for $SIZE$, MTB and LEV in the 8-K sample. In a robustness check, our 8-K results on asymmetric reporting timeliness are valid after including the full set of control variables, but the 8-K results on asymmetric length and tone become statistically weaker.

tion process of 10-Q and 8-K filings. First, we successfully parsed and retrieved 575,579 (1,489,626) unique 10-Q (8-K) filings out of 594,017 (1,628,467) existing filings in EDGAR from 1993-Q1 to 2020-Q1. Next, we merge 10-Q and 8-K dataset with other datasets of firm characteristics and market performance. Finally, we screen the merged 10-Q and 8-K dataset according to the following criteria. We eliminate observations with missing value in key accounting and financial variables or with beginning-of-quarter stock prices below \$1. In 10-Q sample, we further delete observations with missing values in analyst coverage variables. We exclude financial (SIC code between 6000 and 6999) and utility (SIC code between 4900 and 4999) firms because the accounting policy for the former is different from that of other industries, and they are both highly regulated industries which are incomparable to other industries in general. Observations (a) with non-positive total assets or book value of equity or common shares outstanding, or (b) with negative or above 99% percentile reporting time lag,¹⁹ or (c) with below 1% percentile total number of words are dropped. The Gunning fog index is winsorized at 1% and 99% level. In 8-K sample, we further delete observations that are matched to news days that immediately follow another news day, because such news days may merely reflect the reversal in market returns after a dramatic change in the previous day. All financial variables except returns are winsorized at 1% and 99% level to minimize the impact of outliers. Our final 10-Q sample contains 91,606 firm-quarter observations which constitutes of observations from 5,250 unique firms from 1993 to 2016. Our final 8-K sample contains 119,616 firm-day observations which constitutes of observations from 8,261 unique firms from 1993 to 2020. On average, each firm in 8-K sample has two significant news days in a year. Sample size can vary across different model specifications and is noted in each table.

4 Main Results

4.1 Summary Statistics

Table 2 Panel A presents summary statistics for key variables in 10-Q sample. The summary statistics of the raw word count for positive, negative, uncertainty, litigation and modal words in

¹⁹ Before truncation, the maximum lag is 4,069 days, which is filed by CPI Corp in 2007-06-21 to report a quarterly result as of 1996-04-27 (see <https://www.sec.gov/Archives/edgar/containers/fix041/25354/0001140361-07-012753.txt>). We read some of the 10-Q filings with such extremely long reporting lag but do not find an explanation for the unusual delay. In theory 10-Q filings should be filed within 40 or 45 days after fiscal quarter-end, so it remains a puzzle as to why in practice there exists a few accepted filings with such a big delay in EDGAR database. For the purpose of this study we eliminate observations with unusual delay. We also truncate TLAG at 99% percentile in 8-K sample.

10-Q narratives (untabulated) are consistent with the LM 10-Q dataset.²⁰ On average, each 10-Q filing contains 10,937 words, with considerable variation across filings. TONE is negative in general potentially because the LM sentiment word list contains more negative (2,355) than positive (354) words by construction. On average, the 10-Q filings are filed 39 days after fiscal quarter-end, which is one day before the filing deadline for accelerated filers. Moreover, 75% of the 10-Q filings are filed within 44 days after fiscal quarter-end, which is one day before the filing deadline for all other filers. This shows that firms do have discretion in reporting timeliness. The mean of READ is 38, which is higher than the average fog readability score for 10-K in Li (2008), and this is mainly due to some extremely high values even after winsorizing at 99% level. The median of READ is consistent with Li (2008). Since all financial variables but the QRET are winsorized, QRET contains some extremely high and low values. Our main results of 10-Q sustain if we winsorize QRET.

Table 2 Panel B presents summary statistics for key variables in 8-K sample. 8-K filings are more neutral in terms of tone compared to 10-Q filings, with average TONE being almost zero. Also, 8-K filings are more timely responses to news releases, with average TLAG being 15 days, which is 24 days sooner than average 10-Q filings. In more than 75% of our 8-K firm-day observations, there is only one reported 8-K filing per day, and the maximum number of 8-K filings a firm has reported in one day is four. On average, all reported 8-Ks in one day contains 1,339 words in total, which is significantly less than the number of words per 10-Q. Firms report two 8-K items per day on average, with the maximum number being sixteen. Regarding the financial variables, all but DRET and Δ DRET are winsorized, so these two variables contain some extremely high and low values. Our main results of 8-K sustain if we winsorize DRET and Δ DRET.

Table 2 Panel C presents the descriptive statistics of 8-K items before and after August 23 of 2004.²¹ The most commonly reported 8-K items before reform are Item 7 Financial Statements and Exhibits (33.96%), Item 5 Other Events (27.82%) and Item 2 Acquisition or Disposition of Assets (12.70%), whereas after reform the most frequent ones are Item 9.01 Financial Statements and Exhibits (37.53%), Item 2.02 Results of Operations and Financial Condition (18.22%) and Item 8.01 Other Events (9.50%). Voluntary disclosure, which consists of the Item Results of Operations

²⁰ Bill McDonald and Tim Loughran created a dataset containing summary data for each individual 10-X (e.g., 10-K, 10-K/A, 10-Q405, etc.) filing, available at https://sraf.nd.edu/textual-analysis/resources/#LM_10X_Summaries.

²¹ For brevity, we aggregate the sub-items into one 8-K item for observations after August 23 of 2004. For example, Item 1 subsumes Item 1.01, 1.02, 1.03 and 1.04. The same method applies to the rest of 8-K items. We specifically report the descriptive statistics for Item 2.02 because it is a voluntary item. The other two voluntary items 7.01 and 8.01 are the only sub-items in their categories so we do not report them separately.

and Financial Condition, the Item Regulation FD Disclosure and the Item Other Events, makes up for 42.79% (35.73%) of total 8-K items before (after) the 8-K reform. These statistics are consistent with He and Plumlee (2020) and indicate that firms frequently use voluntary 8-K filings to report events that are not explicitly required but the firms consider important to the public. As a general trend, the average length and reporting time lag of 8-K filings reduces substantially in response to the SEC advocacy of plain English writing and shortened reporting deadlines after the 8-K reform. The average tone rises slightly after the 8-K reform simultaneously. There are also significant differences across items in terms of length, tone and reporting time lag. Within the voluntary items, the Other Events is lengthier and more negative than the other two items on average.

Panel D and Panel E of Table 2 present correlation matrix of key variables in 10-Q and 8-K sample, respectively. In Panel D, READ is negatively correlated with NW, suggesting that lengthier 10-Qs may be more readable.

4.2 Is 10-Q Narrative Disclosure Conservative?

Table 3 Panel A presents the regression result of Equation 1. All regressions include firm and time fixed effects to control for unobservable firm characteristics or time trends that may bias our estimation. Furthermore, given that reporting policy of firms within a same industry may be similar, which may lead to high correlations among observations in textual variables such as NW, TLAG and TONE, we cluster standard errors at 4-digit SIC code industry level to correct the potential existence of serial correlation in dependent variables (Petersen, 2009). Our clustering approach yields 375 clusters in 10-Q sample (approximately 244 observations per cluster on average). As predicted by H1, the coefficient of $QRET \times NEG$ is significantly negative for NW, consistent with 10-Q narratives being lengthier in response to bad news than to good news. Also, consistent with H2, the coefficient of $QRET \times NEG$ is significantly positive for TONE, which suggests that the tone of 10-Q narratives are more news-consistent in response to bad news than to good news. However, in contrast to H3, the coefficient of $QRET \times NEG$ is significantly negative for TLAG in Column 5. This result is consistent with prior evidence that managers tend to delay bad news disclosure or report bad news strategically (Kothari, Shu, & Wysocki, 2009; Niessner, 2015; Segal & Segal, 2016). Nevertheless, this coefficient becomes insignificant after controlling for firm fundamentals that influence disclosure in Column 6. Due to the limitations discussed in Section 3.2 about proxying timeliness of narrative disclosure with 10-Q reporting time lag, we interpret the TLAG results

obtained in 10-Q sample only as supplemental evidence on the timeliness of narrative disclosure.

In addition to the main hypotheses, we study whether and how the 10-Q readability varies in response to good versus bad news. This analysis is motivated by the concern that firms strategically respond to bad news with lengthier 10-Qs than to good news to obfuscate the bad news, leading to information overload and lower market efficiency (Chapman et al., 2019). We regress the Gunning fog readability index (READ) on number of words (NW), quarterly returns (QRET), news indicator (NEG) and their interactions to explore the association between length and readability under the context of good versus bad news.

Table 3 Panel B presents the regression results regarding readability, news and length. If managers indeed intentionally obfuscate bad news, then we expect READ to be higher (less readable) in response to bad news than to good news on average. The obfuscation hypothesis predicts a negative coefficient of $QRET \times NEG$ in Column 1 and 2. In contrast to that prediction, the coefficients of $QRET \times NEG$ is significantly positive in Column 1 and 2, suggesting that on average 10-Qs are more readable in response to bad news than to good news. We further explore whether the incremental length in response to bad news relative to good news contributes to lower readability in response to bad news than to good news. If so, we expect the coefficients of $QRET \times NEG \times NW$ to be negative in Column 3 and 4. In contrast to that prediction, the coefficients of $QRET \times NEG \times NW$ is significantly positive in Column 3 and 4. Moreover, the coefficients of NW is significantly positive. Our interpretation is that overall, lengthier 10-Qs are indeed less readable, but the incremental length in response to bad news is associated with a smaller decrease in readability, compared to the same amount of incremental length in response to good news. This implies that firms use shorter but more sentences and less complex but more words in disclosing bad news compared to good news. These results indicate that overall 10-Qs are more readable in response to bad news than to good news, and that the incremental length in bad news disclosure contributes to higher readability. The two indications are inconsistent with the hypothesis that firms strategically respond to bad news with lengthier 10-Qs to obfuscate the bad news.

Overall, the results illustrate that on average 10-Qs are lengthier and more news-consistent in response to bad news than to good news. In addition, firms use lengthier 10-Qs to clarify rather than obfuscate bad news.

4.3 Is 8-K Narrative Disclosure Conservative?

Table 4 Panel A presents the regression result of Equation 2. All regressions include firm and time fixed effects and standard errors are clustered at 4-digit SIC code industry level. Our clustering approach yields 382 clusters in 8-K sample (approximately 313 observations per cluster on average). As predicted by H1, the coefficient of $\Delta DRET \times NEG$ is significantly negative for NW, consistent with 8-K narratives being lengthier in response to bad news than to good news. Also, consistent with H2, the coefficient of $\Delta DRET \times NEG$ is significantly positive for TONE, which suggests that 8-K narratives are more news-consistent in response to bad news than to good news. Notice that due to the limitations discussed in Section 3.2 regarding using 8-K corpora to study the linguistic tone, the tone results obtained in 8-K sample serve only as supplemental evidence on the news-consistency of narrative disclosure. Finally, in line with H3, the coefficient of $QRET \times NEG$ is significantly positive for TLAG, which suggests that 8-K reporting time lag is shorter in response to bad news than to good news—that is, 8-K filings respond to bad news in a more timely manner relative to good news. We repeat the above main analyses using the restricted 8-K sample, in which all observations are subject to four (five) business day 8-K reporting deadline after (before) August 23 of 2004. Our 8-K results remain unchanged (see Table 1 of Online Appendix).

We perform three additional tests to assess the responsiveness of 8-K to good versus bad news, making use of the unique data structure of 8-K filings. First, we test whether firms report more 8-K items per day in response to bad news than to good news by replacing NITEM as the dependent variable in Equation 2. Second, we analyze whether firms are more likely to report more 8-K filings per day in response to bad news by estimating an ordered logistics version of Equation 2 on N8K ($N8K = 1, 2, 3, 4$). Last but not least, we examine whether firms are more likely to report more promptly via 8-K in response to bad news by estimating an ordered logistics version of Equation 2 on TLAG using the restricted 8-K sample. If the 8-K narrative disclosure is conservative, we expect firm to report more 8-K items and 8-K filings per day in response to bad news than to good news, which predicts β_3^{NITEM} and β_3^{N8K} to be significantly negative.

Table 4 Panel B presents the regression results for three additional tests. In line with our predictions, the coefficients of $\Delta DRET \times BN$ are significantly negative for NITEM and N8K, and is significantly positive for TLAG. Column 1 and 2 present the results of NITEM in an ordinary

least square (OLS) regression²² with firm and time fixed effects and clustered standard errors at industry level identified by 4-digit SIC codes. The significantly positive coefficients (0.221 and 0.222) of $\Delta DRET$ shows that for good news, the number of 8-K items reported is positively associated with the magnitude of change in stock returns. Furthermore, β_3^{NITEM} suggests that on average a negative change in returns leads to 0.32 more reported 8-K items than a positive change, which is equivalent to 16% increase based on the mean of 8-K items reported. Column 3 and 4 present results of ordered logistics models for N8K and TLAG. The baseline group of N8K regression is 1. The significantly positive coefficient (1.076) of $\Delta DRET$ shows that for good news, the likelihood of reporting more number of 8-K filings is positively associated with the magnitude of change in stock returns. Moreover, β_3^{N8K} suggests that controlling for the size of daily changes in stock returns, a negative change in returns leads to a 1.358 increase in the log odds of reporting more number of 8-K filings than a positive change. The baseline group of TLAG regression using restricted 8-K sample is 0. Similarly, the significantly negative coefficient (-0.944) of $\Delta DRET$ shows that for good news, the likelihood of reporting in more days (reporting time lag being longer) is negatively associated with the magnitude of change in stock returns. Also, β_3^{TLAG} suggests that on average a negative change in returns leads to a 1.436 decrease in the log odds of reporting time lag being longer than a positive change, consistent with 8-K filings respond more timely to bad news than to good news.

Overall, the results illustrate that 8-K filings are on average lengthier, more news-consistent and more timely in response to bad news than to good news. Moreover, firms are more likely to report more 8-K items and 8-K filings in response to bad news than to good news. All results are consistent with 8-K narrative disclosure being conservative.

4.4 What Kind of Firms Are More Conservative in Narratives?

Now that we find evidence that narrative disclosure is conservative overall, we next study whether and in which direction narrative conservatism systematically varies with conditional conservatism, and what other fundamental firms characteristics contributes to narrative conservatism.

We follow Khan and Watts (2009) to construct the C_SCORE, a firm-quarter measure of conditional conservatism, using the 10-Q sample.²³ Next, we divide the full 10-Q sample into five

²² We choose the OLS model over the ordered logistic model for NITEM because the value of NITEM ranges from 1 to 16, which would create too many cutoffs for the ordered logistic model.

²³ See the C_SCORE construction process and summary statistics in Table 2 of Online Appendix. The summary statistics of C_SCORE and G_SCORE are consistent with Khan and Watts (2009) overall.

quintile groups according to their level of conditional conservatism (C_SCORE), firm size (SIZE), growth opportunities (MTB) and leverage (LEV). We repeat our main analyses as specified by Equation 1 for each of the quintile groups and compare the results across groups.

Table 5 presents the level of narrative conservatism, measured by β_3 in Equation 1, across five quintile groups of conditional conservatism and of other firm characteristics. We do not add control variables in these regressions since some of the control variables, such as SIZE, MTB and LEV, are the expected sources of variation in narrative conservatism that we intend to study. In the C_SCORE panel, the coefficients of QRET \times NEG are significant for the 20%-40%, 40%-60% and 80%-100% quintile groups in terms of length and tone, indicating that the three groups are conservative in disclosure completeness and news-consistency. However, the coefficients are also negatively significant for the first two groups in terms of reporting time lag, suggesting that the first two groups are not conservative in disclosure timeliness. Therefore, we conclude that overall firms with high level of conditional conservatism, as represented by the 80%-100% C_SCORE group, are conservative in narrative disclosure as well. This result suggests that managers consistently apply a conservative reporting policy to both recognition and disclosure, and that the two financial reporting formats complement each other to some extent. In the SIZE panel, narrative conservatism is driven by the smallest (0%-20%) and the largest (80%-100%) firms. Similarly, in the MTB panel, narrative conservatism is driven by the relatively growing firms (20%-40%) and the most mature (80%-100%) firms. However, we do not find a clear pattern in the LEV panel.

5 Additional Analyses

5.1 Narrative Conservatism in MD&A and NFS

We investigate whether and how the narrative conservatism varies in MD&A and NFS. MD&A provides an overall assessment of firm performance through the eyes of management and NFS provide detailed explanation related to each corresponding line item (FASB, 2018b; SEC, 2019). SEC (2019, Topic 9, 9110.2) requires that “MD&A should not consist of generic or boilerplate disclosure. Rather, it should reflect the facts and circumstances specific to each individual registrant.” If the narrative conservatism that we observe is meaningfully driven by managerial discretion rather than boilerplate, which has little information content, then we expect the MD&A narratives to be more conservative than the NFS narratives, because the former contain less boilerplate and managers have more discretion over their format and content.

We extract the MD&A and the NFS from 37,216 10-Q filings and count the number of total words, number of positive and negative words and number of negations in each section for each filing. Then we calculate the logarithm of number of total words (NW_MDA and NW_NFS) and net positive tone per thousand words (TONE_MDA and TONE_NFS) for each filing. Finally, we reestimate Equation 1 replacing TEX by NW_MDA, NW_NFS, TONE_MDA and TONE_NFS and compare their differences. We do not repeat the main analysis for narrative timeliness because the MD&A and the NFS do not differ in timeliness by construction, since they are extracted from the same 10-Q.

Table 6 presents the results of Equation 1 using the MD&A and NFS sections. Column 1, 3 (Column 2, 4) show the results of the MD&A (NFS) section. First, the signs of the coefficients QRET \times NEG in Column 1 and Column 3 are consistent with H1 and H2, confirming that the MD&A narratives are lengthier and more news-consistent in response to bad news than to good news. Second, the coefficients QRET \times NEG of the NFS are not significant different from zero, suggesting that the NFS narratives are not conservative. Overall, these results indicate that our results are driven by the discretionary disclosure rather than boilerplate.

5.2 Narrative Conservatism in Voluntary and Mandatory Disclosure

We examine how narrative conservatism differs across voluntary and mandatory disclosure. Nelson and Pritchard (2016) document that the informativeness of risk factor disclosure from high litigation firms is significantly higher than that from low litigation firms, but only when the disclosure is voluntary. Their results suggest that voluntary disclosure provides a more comprehensive view for risks than mandatory disclosure, potentially because managers have more freedom to determine the content and the rhetoric in voluntary disclosure, and uses less boilerplate in voluntary disclosure. Thus, we expect voluntary disclosure to be more conservative than mandatory disclosure.

We follow He and Plumlee (2020) to measure voluntary and mandatory disclosure using 8-K sample. We divide the full 8-K sample into voluntary and mandatory disclosure subsamples by the 8-K items reported in each observation. We classify an 8-K observation into voluntary disclosure subsample if it contains at least one of the voluntary 8-K items (Items 5, 9, 12 before and Items 8.01, 7.01, 2.02 after the 8-K reform) identified by prior literature (Lerman & Livnat, 2010; He & Plumlee, 2020). Otherwise, we classify it into mandatory disclosure subsample. Then, we regress Equation 2 using the two subsamples.

Table 7 presents the results of Equation 2 using the 8-K voluntary and mandatory disclosure subsamples. Column 1, 3 and 5 (Column 2, 4 and 6) show the results of the voluntary (mandatory) disclosure subsample. First, the signs of the coefficients $\Delta DRET \times NEG$ in Column 1, 3 and 5 are consistent with H1, H2 and H3, suggesting that voluntary disclosure is lengthier, more news-consistent and more timely in response to bad news than to good news. However, for mandatory disclosure the coefficients of $\Delta DRET \times NEG$ in Column 2 and 4 are not significantly different from zero, and only the coefficient in Column 6 is significantly positive. This result suggests that mandatory disclosure is only conservative in terms of narrative timeliness. Second, the significant differences in the coefficients $\Delta DRET \times NEG$ between the two types of disclosure indicate that voluntary disclosure is more conservative than mandatory disclosure in narratives, consistent with Nelson and Pritchard (2016) that voluntary disclosure is more informative about firm risk.

5.3 Managerial Incentives and Narrative Conservatism

We inspect how narrative conservatism varies in three setting where managers have strong incentives to disclose or withhold bad news. First, when firms announce a seasoned equity offering (SEO), managers have incentives to manipulate investor perceptions upward through earnings numbers (Teoh et al., 1998) and through disclosure (Lang & Lundholm, 2000). Similarly, we expect managers to be less conservative in narrative disclosure under a SEO. Second, when executives anticipate a high value stock option grant, they have incentives to disclose bad news prior to the grant to ensure a lower option exercise price at the grant date (Aboody & Kasznik, 2000; Baker, Collins, & Reitenga, 2003; McAnally, Srivastava, & Weaver, 2008). Therefore, we expect narrative disclosure to be more conservative when firms grant stock option of high value to their executives. The third setting is when firms are under high litigation risk, for which we do not have an ex-ante prediction because prior literature documents mixed evidence regarding its impact on managerial incentives to disclose bad news. On the one hand, when firms face high litigation risk, managers may have incentives to disclose bad news voluntarily to avoid being sued or to reduce the cost of resolving litigation that inevitably follows in bad news quarters (Skinner, 1994, 1997). On the other hand, bad news disclosure may trigger litigation (Francis et al., 1994), which provides managers strong incentives to withhold bad news to avoid litigation (Rogers & Van Buskirk, 2009). Although it is inconclusive as to whether high litigation motivates managers to disclose or withhold bad news, we are still interested in this setting since prior literature generally recognize litigation as an important determinant of disclosure.

To test the SEO setting, we use Sale of Common and Preferred Stock (SSTKY) data from Compustat from 1993 to 2020. We drop all observations with missing or negative SSTKY and we classify the observations with zero SSTKY into non-SEO subsample. Then we divide the full 10-Q sample into five subsamples according to the SSTKY of each observation, and we label the subsample with above 80% percentile SSTKY as SEO subsample. We reestimate Equation 1 using the non-SEO and SEO subsamples and compare their results. To test the stock option grants setting, we collect stock option grant data from ExecuComp from 1993 to 2006. We sum up the Black Scholes fair value of stock options granted to each individual executive (BLKSHVAL) by firm-year to create a measure of the value of stock options granted to executives for a given firm in a given year (BLKSHVALSUM). Then we match the stock option grant data to our 10-Q data by GVKEY and fiscal year and we drop all unmatched observations and matched observations with non-positive or missing BLKSHVALSUM. Finally we divide the full 10-Q sample into two subsamples according to the BLKSHVALSUM of each observation, and we label the subsample with below (above) median BLKSHVALSUM as low (high) stock option value subsample. We reestimate Equation 1 using the low and high stock option value subsamples and compare their results. To test the litigation risk setting, we classify firms into low and high litigation risk subsamples by their industry membership (Francis et al., 1994; Kim & Skinner, 2012). Specifically, we deem the firms in the biotech (SIC codes 2833–2836 and 8731–8734), computer (3570–3577 and 7370–7374), electronics (3600–3674), or retail (5200–5961) industry as having high litigation risk, and the other firms as having low litigation risk. We reestimate Equation 1 using the low and high litigation subsamples and compare their results.

Table 8 Panel A presents the results of Equation 1 using non-SEO and SEO subsamples. Comparing the results between the non-SEO and SEO subsamples, the SEO firms are slightly more conservative in terms of completeness, but are much less conservative in terms of news-consistency than non-SEO firms. We interpret the results as that overall the firms that are undergoing SEO are less conservative than those that are not, consistent with managers being less conservative when they have strong incentives to withhold bad news. Table 8 Panel B presents the results of Equation 1 using low and high value stock option grant subsamples. Only the firms that issue high value stock option grants are conservative in terms of completeness, consistent with managers being more conservative when they have strong incentives to disclose bad news. Table 8 Panel C presents the results of Equation 1 using low and high litigation risk subsamples. Firms with high litigation risk are conservative, but to a lesser degree compared to firms with low litigation risk in terms

of completeness and news-consistency. Our evidence of firms under high litigation risk being less conservative in narrative disclosure is consistent with the finding of Rogers and Van Buskirk (2009) that firms reduce the frequency and amount of disclosure to avoid litigation. Our finding also provides indirect support to Francis et al. (1994) that bad news disclosure may trigger litigation.

5.4 Reg FD - DiD

5.5 Bundling

5.6 Robustness Checks

We conduct a battery of robustness checks. First, to ensure that our asymmetric narrative tone results are not driven by the choice of dictionary (Loughran & McDonald, 2016), we use the Harvard General Inquirer word list²⁴ (e.g., Tetlock, 2007; Kothari, Li, & Short, 2009) to generate the raw count of positive and negative words per document and reconstruct the tone measure for 10-Q filings. Our results on 10-Q asymmetric tone are robust to the alternative tone measure. Second, to ensure that our results are not driven by omitted factors that affect stock returns and disclosure behavior, we include firm size, growth opportunities, leverage, conditional conservatism, seasoned equity offerings, stock option grants and litigation risk as controls and our 10-Q results on asymmetric length and tone sustain. Our 8-K results on asymmetric timeliness are also robust (a) after controlling for firm size, growth opportunities, leverage, earnings, operating risks, volatilities, business complexity and analyst expectations of future financial performance or (b) after excluding 8-K days that contain information on results of operations, i.e., quarterly or annual earnings (Segal & Segal, 2016).

Figure 1: 8-K Matching Process

Figure 1 illustrates the 8-K sample matching process. We match every 8-K day to its nearest news day. The news day can be earlier than (Match-1), the same as (Match-2) or later than (Match-3) the 8-K day. TLAG is defined as the number of days elapsed between the 8-K filing date and its nearest news day.

Table 1. Sample Selection Process

		10-Q
Nuner of observations:		
Retrieved from EDGAR		575,579
After merging with COMP and CRSP data		303,034
(-) Number of obs. from utility and financial firms		82,612
(-) Number of firm-quarters with missing values in SIC, SIZE, MTB, LEV, or with non-positive total assets or book value of equity or common shares outstanding, or with common share price less than \$1		26,450
(-) Number of obs. with total words less than 1% percentile (1,236 words)		1,940
(-) Number of obs. that contain negative or larger than 99% TLAG		1,696
After dropping obs. with missing values in key variables and screening		190,336
After merging with I\B\E\S and segment data		110,062
(-) Number of obs. that contain missing EARN, STD_EARN and AF		18,456
Full 10-Q sample		91,606
		8-K
Nuner of observations:		
Retrieved from EDGAR		1,489,620
After merging and matching with COMP and CRSP data		442,611
(-) Number of obs. from utility and financial firms		112,739
(-) Number of firm-quarters with missing values in SIC, SIZE, MTB, LEV, or with non-positive total assets or book value of equity or common shares outstanding, or with common share price less than \$1		48,230
(-) Number of obs. with total words less than 1% percentile (133 words)		2,776
(-) Number of obs. that are reversals of previous news day		5,132
After dropping obs. with missing values in key variables and screening		273,734
After dropping obs. with negative or larger than 99% percentile TLAG		
(Full 8-K sample)		119,616
After dropping obs. with TLAG larger than four (five) days after (before) the 8-K reform		
(Restricted 8-K sample)		40,700

Table 2 Panel C presents the descriptive statistics of key textual variables by 8-K items. Number of appearance represents the total number of times that each 8-K item is reported. Percentage of appearance represents the percentage of each 8-K item calculated based on the number of appearance. See Appendix B for other variable definitions. Column nw, TONE and TLAG report the mean value of the corresponding variable in each 8-K item group. See Appendix A for 8-K item descriptions. Voluntary 8-K items are in bold.

\end{aligned}$$

Table 3 Panel B presents the regression results of the above models. CONTROLS denotes a vector of control variables, including SIZE, MTB, LEV, EARN, STD_RET, STD_EARN, AGE, BUGSSEG, GEOSSEG, AF, AFE. See Appendix B for variable definitions. READ and all financial variables except returns are winsorized at 1% and 99% level. All regressions include firm and time fixed effects and standard errors are clustered at industry level identified by 4-digit SIC codes. ***, ** and * indicate significance at the 1%, 5% and 10% levels in a two-tailed test.

Table 5 presents the level of narrative conservatism (β_3 in Equation 1) across five quantile groups of conditional conservatism and of other firm characteristics. TEX represents a vector of textual properties that consists of number of words (NW), tone (TONE) and reporting time lag (TLAG). See Appendix B for variable definitions. All financial variables except returns are winsorized at 1% and 99% level. All regressions include firm and time fixed effects. ***, ** and * indicate significance at the 1%, 5% and 10% levels in a two-tailed test.

Table 8 Panel A, Panel B and Panel C present the regression results of Equation 1 using subsamples under seasoned equity offering, stock options grants, and litigation risk settings respectively. TEX represents a vector of textual properties that consists of NW, TONE and TLAG. All regressions control for SIZE, MTB, LEV, EARN, STD_RET, STD_EARN, AGE, BUSSEG, GEOSEG, AFE and AF (untabulated). See Appendix B for variable definitions. All financial variables except returns are winsorized at 1% and 99% level. All regressions include firm and time fixed effects and standard errors are clustered at industry level identified by 4-digit SIC codes. ***, ** and * indicate significance at the 1%, 5% and 10% levels in a two-tailed test.

Appendix

Appendix A: 8-K Item List

8-K Item List Before 2004-08-23

- | | |
|---------|---|
| Item 1 | Changes in Control of Registrant |
| Item 2 | Acquisition or Disposition of Assets |
| Item 3 | Bankruptcy or Receivership |
| Item 4 | Changes in Registrant's Certifying Accountant |
| Item 5 | Other Events |
| Item 6 | Resignation of Registrant's Directors |
| Item 7 | Financial Statements and Exhibits |
| Item 8 | Change in Fiscal Year |
| Item 9 | Regulation FD Disclosure |
| Item 10 | Amendments to the Registrant's Code of Ethics |
| Item 11 | Temporary Suspension of Trading Under Registrant's Employee Benefit Plans |
| Item 12 | Results of Operations and Financial Condition |

8-K Item List After 2004-08-23 (included)

Section 1 Registrant's Business and Operations

- Item 1.01 Entry into a Material Definitive Agreement
- Item 1.02 Termination of a Material Definitive Agreement
- Item 1.03 Bankruptcy or Receivership
- Item 1.04 Mine Safety - Reporting of Shutdowns and Patterns of Violations

Section 2 Financial Information

- Item 2.01 Completion of Acquisition or Disposition of Assets
- Item 2.02 Results of Operations and Financial Condition
- Item 2.03 Creation of a Direct Financial Obligation or an Obligation under an Off-Balance Sheet Arrangement of a Registrant
- Item 2.04 Triggering Events That Accelerate or Increase a Direct Financial Obligation or an Obligation under an Off-Balance Sheet Arrangement
- Item 2.05 Costs Associated with Exit or Disposal Activities
- Item 2.06 Material Impairments

Section 3 Securities and Trading Markets

- Item 3.01 Notice of Delisting or Failure to Satisfy a Continued Listing Rule or Standard; Transfer of Listing
- Item 3.02 Unregistered Sales of Equity Securities
- Item 3.03 Material Modification to Rights of Security Holders

Section 4 Matters Related to Accountants and Financial Statements

- Item 4.01 Changes in Registrant's Certifying Accountant
- Item 4.02 Non-Reliance on Previously Issued Financial Statements or a Related Audit Report or Completed Interim Review

Section 5 Corporate Governance and Management

- Item 5.01 Changes in Control of Registrant
- Item 5.02 Departure of Directors or Certain Officers; Election of Directors; Appointment of Certain Officers; Compensatory Arrangements of Certain Officers
- Item 5.03 Amendments to Articles of Incorporation or Bylaws; Change in Fiscal Year
- Item 5.04 Temporary Suspension of Trading Under Registrant's Employee Benefit Plans
- Item 5.05 Amendment to Registrant's Code of Ethics, or Waiver of a Provision of the Code of Ethics
- Item 5.06 Change in Shell Company Status
- Item 5.07 Submission of Matters to a Vote of Security Holders
- Item 5.08 Shareholder Director Nominations

Section 6 Asset-Backed Securities

- Item 6.01 ABS Informational and Computational Material
- Item 6.02 Change of Servicer or Trustee
- Item 6.03 Change in Credit Enhancement or Other External Support
- Item 6.04 Failure to Make a Required Distribution
- Item 6.05 Securities Act Updating Disclosure

Section 7 Regulation FD

- Item 7.01 Regulation FD Disclosure

Section 8 Other Events

- Item 8.01 Other Events

Section 9 Financial Statements and Exhibits

- Item 9.01 Financial Statements and Exhibits

Voluntary items:

- (1) Other Events (Item 5 and Item 8.01)
- (2) Regulation FD Disclosure (Item 9 and Item 7.01)
- (3) Results of Operations and Financial Condition (Item 12 and Item 2.02)

Appendix B: Variable Definition

Textual Variables

Variable	Definition
NW	Number of words, defined as the natural logarithm of one plus the count of total words (nw)
nw	Raw count of total words
TONE	Tone, defined as the number of net positive words per thousand total words, calculated as the total number of positive words minus the sum of total number of negative words and the total number of negations, and multiply the previous result by one thousand
TLAG	Time lag, defined as the number of natural days elapsed between the news release date and the document filing date. In 10-Q sample, it is the number of natural days elapsed between the fiscal quarter-end date and the 10-Q filing date in EDGAR. In 8-K sample, it is the number of natural days elapsed between the 8-K filing date and its nearest news day, defined as a date whose change in daily return ($\Delta DRET$) is three times larger than the firm's average change in daily return over the calendar year
READ	Gunning fog index, calculated as the average words per sentence plus the percent of complex words and multiply the sum by 0.4
N8K	Number of 8-K filings in one reporting period date
NITEM	Number of 8-K items in one reporting period date

Financial Variables

Variable	Definition
EARN	Quarterly earnings, defined as quarterly earnings before extraordinary items (Compustat data item IBQ) scaled by beginning-of-quarter total assets (Compustat data item ATQ)
LEV	Leverage ratio, defined as beginning-of-quarter short term debt (Compustat data item DLCQ) plus beginning-of-quarter long term debt (Compustat data item DLTQ) scaled by beginning-of-quarter total assets (Compustat data item ATQ)
MTB	Market-to-book ratio, defined as beginning-of-quarter market value of equity, calculated as common share price (Compustat data item PRCCQ) times common shares outstanding (Compustat data item CSHOQ) divided by beginning-of-quarter book value of equity (Compustat data item CEQQ)
SIZE	Firm size, defined as the natural logarithm of market value of equity, calculated as natural logarithm of common share price (Compustat data item PRCCQ) times common shares outstanding (Compustat data item CSHOQ)
QRET	Quarterly market-adjusted stock return, defined as buy-and-hold stock return (CRSP data item RET) over the fiscal quarter adjusted by the value-weighted stock return (CRSP data item VWRETD) over the same period
DRET	Daily market-adjusted stock return, defined as daily buy-and-hold stock return (CRSP data item RET) adjusted by the daily value-weighted stock return (CRSP data item VWRETD)
Δ DRET	Change in daily market-adjusted stock return (DRET), defined as current daily market-adjusted stock return minus one-day-lagged daily market-adjusted stock return
NEG	Indicator for negative quarterly return, which is set to 1 when market-adjusted stock return (QRET) is negative and 0 otherwise
BN	Indicator for daily bad news, which is set to 1 (0) if the negative (positive) change in daily market-adjusted stock return (Δ DRET) is three times larger than the firm's average decrease (increase) in daily return over the calendar year.
AF	Analyst forecast, defined as analysts' mean consensus forecast for one-year-ahead earnings per share, scaled by stock price per share at the end of the fiscal quarter (Compustat data item PRCCQ)
AFE	Analyst forecast error, defined as I/B/E/S earnings per share minus the median of the most recent analysts' forecasts, deflated by stock price per share at the end of the fiscal quarter (Compustat data item PRCCQ)
BUSSEG	Business segment, defined as the natural logarithm of one plus number of business segments, or one if item is missing from Compustat
GEOSEG	Geographical segment, defined as the natural logarithm of one plus number of geographical segments, or one if item is missing from Compustat
AGE	Firm age, defined as the natural logarithm of one plus number of days elapsed since the firm's first entry date in CRSP
STD_EARN	Standard deviation of quarterly earnings (EARN) over the last five quarters
STD_QRET	Standard deviation of monthly market-adjusted stock return over all months in the fiscal quarter

Appendix C: 8-K Matching Cases

We check whether the 8-K filings are responses to their matched news releases, as proxied by dramatic market movements. First, we randomly pick 20 good and bad news events. Next, we read the 8-Ks matched to the news and check if the corporate events depicted in the 8-Ks are in line with the market movements both in terms of direction and magnitude. We find that the 8-K matching cases make economic sense overall. See selected 8-K matching cases below.

Good News

Case 1: Drug Test Results Announcement; TLAG = 2

Opexa Therapeutics, Inc. (CIK = 0001069308) experienced a significant rise in market-adjusted daily stock returns ($\Delta\text{DRET} = 2.67$) on September 8 of 2009. On September 10 of 2009, the company filed an 8-K with ending reporting period on September 8 of 2009, which contained Item 8.01: Other Events and Item 9.01: Financial Statements and Exhibits. This 8-K stated that “On September 8, 2009, Opexa Therapeutics, Inc. (the ‘Company’) issued a press release reporting additional analyses of TERMS data for Tovaxin®, a personalized T-cell immunotherapy for multiple sclerosis (MS)”.

Case 2: Sales of Equity Securities; TLAG = 6

MiddleBrook Pharmaceuticals, Inc. (CIK = 0001161924) experienced a significant rise in market-adjusted daily stock returns ($\Delta\text{DRET} = 1.43$) on January 24 of 2008. On January 30 of 2008, the company filed an 8-K with ending reporting period on January 24 of 2008, which contained Item 1.01: Entry into a Material Definitive Agreement, Item 3.02: Unregistered Sales of Equity Securities and Item 9.01: Financial Statements and Exhibits. This 8-K stated that “On January 24, 2008, Middlebrook Pharmaceuticals, Inc. (the ‘Company’) entered into a Securities Purchase Agreement (the ‘Securities Purchase Agreement’) with selected accredited investors (the ‘Investors’), to sell an aggregate of approximately 8,750,000 shares (the ‘Shares’) of the Company’s common stock, par value \$0.01 per share (the ‘Common Stock’), and warrants to purchase an aggregate of approximately 3,500,000 shares of Common Stock (the ‘Warrant Shares’) at an exercise price of \$3.00, subject to certain adjustments (the ‘Warrants’ and, together with the Shares, the ‘Units’), at a price of \$2.40 per Unit, resulting in gross proceeds to the Company of \$21 million (the ‘Offering’)”.

Case 3: Entry into an Agreement; TLAG = 6

SinoCoking Coal and Coke Chemical Industries, Inc. (CIK = 0001099290) experienced a significant rise in market-adjusted daily stock returns ($\Delta\text{DRET} = 1.38$) on September 9 of 2014. On September 15 of 2014, the company filed an 8-K with ending reporting period on September 9 of 2014, which contained Item 8.01: Other Events and Item 9.01: Financial Statements and Exhibits. This 8-K included a press release, which stated that “SinoCoking Coal and Coke Chemical Industries, Inc. (Nasdaq:SCOK), a vertically-integrated coal and coke processor, today said it has signed an exclusive agreement with both the Institute of Process Engineering of the Chinese Academy of Sciences and the North China Institute of Science and Technology to refine and implement a technology that will be used, beginning next month, to convert the 21 million tons of coal at four SinoCoking underground mines into syngas, a clean burning fuel”.

Case 4: Entry into a Material Definitive Agreement; TLAG = 8

E-Net, Inc. (CIK = 0001012481) experienced a significant rise in market-adjusted daily stock returns ($\Delta\text{DRET} = 1.19$) on September 15 of 1999. On September 23 of 1999, the company filed an 8-Ks with ending reporting period on September 15 of 1999. The 8-K contained Item 5: Other events and Item 7: Financial statements and exhibits. The 8-K stated that “E-Net, Inc. (Nasdaq: ETEL) and IXC Communications, Inc. (Nasdaq: IIXC) have signed a definitive agreement to jointly develop and market the Internet Telephony services of e-Net’s wholly owned subsidiary, ZeroPlus.com, Inc., to consumers and businesses around the world”.

Case 5: Sales of Equity Securities; TLAG = 6

ReWalk Robotics Ltd. (CIK = 0001607962) experienced a significant rise in market-adjusted daily stock returns ($\Delta\text{DRET} = 1.19$) on June 5 of 2019. On June 11 of 2019, the company filed an 8-K with ending reporting period on June 5 of 2019, which contained Item 1.01: Entry into a Material Definitive Agreement, Item 3.02: Unregistered Sales of Equity Securities, Item 8.01: Other Events and Item 9.01: Financial Statements and Exhibits. This 8-K stated that “On June 5, 2019 and June 6, 2019, ReWalk Robotics Ltd. (the ‘Company’) entered into warrant exercise agreements (the ‘Exercise Agreements’) with certain institutional investors (the ‘Holders’) of warrants to purchase the Company’s ordinary shares (the ‘Public Warrants’), par value NIS 0.25 per share (the ‘Ordinary Shares’), previously issued in the Company’s follow-on offering in November 2018, pursuant to which the Holders agreed to exercise in cash their Public Warrants to purchase an aggregate of 1,464,665 Ordinary Shares at the existing exercise price of \$7.50 per share, for gross proceeds (before placement agent fees and expenses of approximately \$1 million) to the Company of approximately \$11 million”.

Bad News

Case 1: Disposition of Assets; TLAG = 1

Media Services Group, Inc. (CIK = 0000014280) experienced a significant drop in market-adjusted daily stock returns ($\Delta\text{DRET} = -3.26$) on April 13 of 2004. On April 14 of 2004, the company filed an 8-K with ending reporting period on the same day, which contained Item 2: Acquisition or disposition of assets. This 8-K stated that “On March 31, 2004, Media Services Group, Inc. (the ‘Company’) completed its sale of substantially all of the assets relating to its tele-marketing sales and teleservices business held by its wholly-owned subsidiary, MKTG Teleservices, Inc. to SD&A Teleservices, Inc. (‘SD&A’), a Georgia corporation and wholly-owned subsidiary of the Robert W. Woodruff Arts Center, Inc. for \$3.3 million in cash plus the assumption of certain liabilities relating to such business, subject to a final working capital adjustment, pursuant to a definitive agreement entered into as of March 31, 2004”.

Case 2: Termination of a Material Definitive Agreement; TLAG = 0

Ocean Power Technologies, Inc. (CIK = 0001378140) experienced a significant drop in market-adjusted daily stock returns ($\Delta\text{DRET} = -3.26$) on June 2 of 2016. On June 2 of 2016, the company filed two 8-Ks with ending reporting period on the same day, which contained Item 1.02: Termination of a Material Definitive Agreement, Item 1.01: Entry into a Material Definitive Agreement and Item 9.01: Financial Statements and Exhibits. The first 8-K stated that “On June 2, 2016, Ocean Power Technologies, Inc. (the ‘Company’) and Rodman & Renshaw, a unit of H. C. Wainwright & Co., LLC (the ‘Manager’), agreed to terminate the At the Market Offering Agreement

(the ‘Offering Agreement’) dated October 19, 2015, as amended, between the Company and the Manager, relating to the offering and sale of shares of the Company’s common stock, par value \$0.001 per share, having an aggregate offering price of up to \$2,906,836 from time to time through or to the Manager, in an ‘at the market offering.’ The termination of the Offering Agreement is effective immediately and the at the market offering program is no longer available for use by the Company”.

Case 3: Departure of Directors or Certain Officers; TLAG = 0

Catuity Inc. (CIK = 0001109740) experienced a significant drop in market-adjusted daily stock returns ($\Delta\text{DRET} = -3.16$) on June 22 of 2005. On June 22 of 2005, the company filed an 8-K with ending reporting period on the same day, which contained Item 5.02: Departure of Directors or Certain Officers; Election of Directors; Appointment of Certain Officers: Compensatory Arrangements of Certain Officers. This 8-K stated that “On Friday June 17, 2005 Catuity learned of the unfortunate and unexpected death of Mr. Alan L. Gilman, one of the Company’s members of its Board of Directors. Mr. Gilman died of a heart attack despite having no history of heart trouble”.

Case 4: Vote of Security Holders; TLAG = 4

Biostar Pharmaceuticals, Inc. (CIK = 0001418133) experienced a significant drop in market-adjusted daily stock returns ($\Delta\text{DRET} = -2.19$) on June 9 of 2016. On June 13 of 2016, the company filed an 8-K with ending reporting period on June 9 of 2016, which contained Item 5.07: Submission of Matters to a Vote of Security Holders. This 8-K stated that “On June 9, 2016, Biostar Pharmaceuticals, Inc. (the ‘Company’) held its Annual Meeting of Shareholders at its executive offices in Xianyang City, Shaanxi Province, People’s Republic of China. Set forth below are the matters voted upon at the meeting and the voting results. On the record date of April 13, 2016, there were 2,212,188 shares of the Company’s common stock issued and outstanding. Proposal 1 (Election of Directors) - The shareholders elected Ronghua Wang, King-fai Leung, Haipeng Wu, Zhongyang Shang and Qinghua Liu as directors of the Company to hold office until the next annual meeting of shareholders and until their successors are duly elected. Proposal 2 (Ratification of Auditors) - The Company’s shareholders voted to ratify the appointment of Mazars CPA Limited as the Company’s independent registered public accounting firm for the year ending December 31, 2015 with 1,510,989 shares voting for and 25,326 shares voting against (15,431 shares abstaining)”.

Case 5: Receiving a Request for Clarification from the Stock Exchange; TLAG = 3

My Size, Inc. (CIK = 0001211805) experienced a significant drop in market-adjusted daily stock returns ($\Delta\text{DRET} = -1.86$) on February 14 of 2017. On February 17 of 2017, the company filed an 8-K with ending reporting period on February 14 of 2017, which contained Item 8.01: Other Events and Item 9.01: Financial Statements and Exhibits. This 8-K stated that “On February 14, 2017, the Company received a verbal request from the Tel Aviv Stock Exchange to clarify to the public the difficulties which hindered the possibility of transferring the Company’s shares from market to market. In response to such request, the Company filed a report which contained the following statement...”

Appendix D: 10-Q and 8-K parsing

We develop a Python program to automatically parse, process and retrieve 10-K and 8-K filings from EDGAR database. Our algorithm consists of the following steps:

1. Download all quarterly master indexes from EDGAR using *python-edgar*²⁵ package.
2. Filter all 10-Q and 8-K filings²⁶ from EDGAR master index files and obtain the url of the *filing detail* webpage²⁷ for each of the 10-Q and 8-K filings.
3. Extract (a) the identification information²⁸ and (b) the url of report in HTM/TXT format²⁹ from the *filing detail* webpage for each of the 10-Q and 8-K filings.
4. Parse and cleanse³⁰ all 10-Q and 8-K filings with url of HTM/TXT format report, using *beautiful soup*³¹ package.
5. Save all clean 10-Q and 8-K filings to local device.
6. Perform word count on clean 10-Q and 8-K filings using LM dictionary.³²
7. Calculate the Gunning fog index using *textstat*³³ package.

All Python scripts and data are available online via https://github.com/fengzhi22/narrative_conservatism.

²⁵ Python-edgar package documentation available at <https://github.com/edouardswiac/python-edgar>

²⁶ Our analyses exclude amendments such as 10-Q/A and 8-K/A

²⁷ One example of filing detail webpage is available at <https://www.sec.gov/Archives/edgar/data/320193/000032019320000050/0000320193-20-000050-index.html>

²⁸ For example cik, accession number, reporting period, filing date and 8-K items etc.

²⁹ One example of report in HTM format is available at <https://www.sec.gov/Archives/edgar/data/320193/000032019320000050/a8-kq220203282020.htm>. We first search for url of main report in HTM format. If HTM format main report is not available, then we extract the url of TXT format full report. Each EDGAR filing can be accessed in three formats at maximum: regular text (*.txt), web pages (*.htm) and eXtensible Business Reporting Language, also known as XBRL (*.xml). Early filings in EDGAR are only in TXT format. Later filings extend to HTM format, and in 2009 the SEC adopted the XBRL for all corporate filings (SEC, 2009). Therefore, current existing EDGAR filings all contain a TXT file, and depending on their filing date and company reporting policy they may or may not contain HTM or XML files. Normally all filings in XML format are also available in HTM format. We manually checked 100 random filings that are in XML format, and all of them are also available in HTM format with the same content. The TXT files usually contain not only the main report, but also all other additional filing materials (if any) such as graphics, exhibits and press release etc. However, the HTM files only contain the main report. We mainly focus on the HTM files other than the TXT files because the former naturally filters out less relevant information, and provides a cleaner textual content of the essential information. XML files are not parsed due to low tractability.

³⁰ Cleansing steps are: (a) delete nondisplay section; (b) delete all tables that contains more than 4 numbers; and (c) delete all HTML tags

³¹ Beautiful soup package documentation available at <https://www.crummy.com/software/BeautifulSoup/bs4/doc/>

³² LM dictionary available at <https://sraf.nd.edu/textual-analysis/resources/#LM%20Sentiment%20Word%20Lists>

³³ textstat package documentation available at <https://github.com/shivam5992/textstat>

$$TEX_{i,t} = \beta_0 + \beta_1 \Delta DRET_{i,t-tlag} + \beta_2 BN_{i,t-tlag} + \beta_3 \Delta DRET_{i,t-tlag} \times BN_{i,t-tlag} + \beta_n CONTROLS_{i,t} + \epsilon_{i,t} \quad (2)$$

Online Appendix Table 1 presents regression results of Equation (2) using restricted 8-K sample. All observations in restricted 8-K sample are subject to four (five) business day 8-K reporting deadline after (before) August 23 of 2004. TEX represents a vector of textual properties that consists of number of words (NW), tone (TONE) and reporting time lag (TLAG). $CONTROLS$ denotes a vector of control variables, including SIZE, MTB and LEV. See Appendix B for variable definitions. All financial variables except returns are winsorized at 1% and 99% level. All regressions include firm and time fixed effects and standard errors are clustered at industry level identified by 4-digit SIC codes. ***, ** and * indicate significance at the 1%, 5% and 10% levels in a two-tailed test.

Online Appendix. Table 2.

Panel B: Summary Statistics of C_SCORE and G_SCORE

	mean	median	std. dev	max	min	p1	p25	p75	p99
C_SCORE	0.053	0.054	0.063	1.143	-0.228	-0.103	0.015	0.092	0.212
G_SCORE	-0.008	-0.008	0.031	0.188	-1.314	-0.091	-0.023	0.009	0.067

$$\begin{aligned}
EARN_{i,t} = & \beta_0 + \beta_1 NEG_{i,t} + \beta_2 RET_{i,t} \\
& + \beta_3 RET_{i,t} \times SIZE_{i,t} + \beta_4 RET_{i,t} \times MTB_{i,t} + \beta_5 RET_{i,t} \times LEV_{i,t} + \beta_6 RET_{i,t} \times NEG_{i,t} \\
& + \beta_7 RET_{i,t} \times NEG_{i,t} \times SIZE_{i,t} + \beta_8 RET_{i,t} \times NEG_{i,t} \times MTB_{i,t} + \beta_9 RET_{i,t} \times NEG_{i,t} \times LEV_{i,t} \\
& + \beta_{10} SIZE_{i,t} + \beta_{11} MTB_{i,t} + \beta_{12} LEV_{i,t} \\
& + \beta_{13} NEG_{i,t} \times SIZE_{i,t} + \beta_{14} NEG_{i,t} \times MTB_{i,t} + \beta_{15} NEG_{i,t} \times LEV_{i,t} + \epsilon_{i,t}
\end{aligned} \tag{3}$$

$$C_SCORE_{i,t} = \beta_6 + \beta_7 SIZE_{i,t} + \beta_8 MTB_{i,t} + \beta_9 LEV_{i,t} \tag{4}$$

$$G_SCORE_{i,t} = \beta_2 + \beta_3 SIZE_{i,t} + \beta_4 MTB_{i,t} + \beta_5 LEV_{i,t} \tag{5}$$

Online Appendix Table 2 presents the key statistics in constructing C_SCORE and G_SCORE. Panel A presents the mean of coefficients, the mean of standard errors and the t-statistics obtained from 23 fiscal yearly regressions (Equation 3) using 10-Q sample from 1993 to 2015. C_SCORE and G_SCORE are calculated following Equation 4 and Equation 5 respectively. Panel B presents the summary statistics of C_SCORE and G_SCORE. See Appendix B for variable definitions. All financial variables except returns are winsorized at 1% and 99% level. The mean and standard errors of coefficients and the summary statistics of C_SCORE and G_SCORE are consistent with Khan and Watts (2009) overall.
